Construction of the Patent Quality Index

This appendix provides further information on the construction of the patent quality index used in this study to capture the value of an invention (see also Ernst et al. (2014)). The methodology follows Hall et al. (2007) and Lanjouw and Schankerman (2004). The data we use in our estimations is obtained from Grid Thoma. Previous studies document evidence that patent value strongly varies across patent applications (e.g. Harhoff et al. (1999)). While in the past many different indicators have been used to measure patent value, more recent literature suggests to combine several indicators within a composite measure (see Lanjouw and Schankerman (2004)) by means of factor analysis. Factor analysis allows to filter out idiosyncratic shocks contained in each single indicator to retain only a common shock that influences all included factors. The so obtained common factor is then used in the empirical analysis as the composite quality index. A main underlying assumption to factor analysis is that the variance in each indicator may be traced back to a common factor that influences all indicators and an idiosyncratic component which is independent of the other indicators and may only impact one indicator.

The general factor model is denoted:

$$y_{kn} = \alpha_k \nu_n + \beta X_n + \epsilon_{kn} \quad (8)$$

1
2
3 where y_{kn} is the observation of the k 'th patent indicator for the n 'th
4 patent, ν_n is the common factor (here: patent quality) that is assumed to
5 be normally distributed, α_k is the factor loading obtained and X_n is a
6 vector of control variables. The factor loading determines the impact of
7 the common factor on the patent indicators. Taken together, the common
8 factor multiplied with the corresponding factor loadings is the common
9 component K . Estimating the common factor is a minimization problem
10 of the idiosyncratic term, where a linear combination of the indicators
11 that explains as much as possible the total variance of each indicator
12 has to be identified. The common factor ν , however, is unobservable
13 and therefore, no unique solution to the problem exists. To extract the
14 common factor, principal components analysis is used. By means of
15 principal components analysis, the data on y_{kn} is used to determine the
16 first V eigenvalues and eigenvectors from the variance-covariance matrix.
17
18 The common component is defined as $K = XVV'$, where $V = [p_1, \dots, p_v]$
19 and p_i is the eigenvector corresponding to the i 'th largest ($i = 1, \dots, Q$)
20 eigenvalue of the covariance matrix of X . After having extracted the
21 common component only the idiosyncratic term ϵ_{kn} remains.
22
23

24 The indicators we include in the analysis are family size, forward
25 citations and technological classes. The common factor influences all
26 three separate indicators of patent quality and eventually will be our
27 multidimensional quality measure. The data we use to determine the
28 common factor is information on the total number of patents granted at
29

1
2
3 the EPO. The *family size* of a patent covers all countries where patent
4 protection is sought. When applying for patent protection at the EPO
5 directly, the patentee may select the countries where the intellectual
6 property right should be protected. These will be the countries where the
7 patentee wants to use the patent in the production process and where
8 the products are ultimately sold to the consumer. Since the cost for
9 patent application increases in the number of countries where protection is
10 sought, a firm will only apply in several countries if it expects the profits
11 to outweigh the cost. Consequently, the size of a patents' family can be
12 interpreted as an indicator of the patent's quality and its future earnings
13 potential. For the construction of the measure, note that PATSTAT also
14 contains information on patent applications to the US patent office and all
15 other major national patent offices. This information is used to identify
16 equivalent applications filed outside of the EPO at an earlier time (priority
17 applications). In a first step, all priorities for the EPO patents were
18 identified. In a second step, all applications that report the EPO application
19 as a priority were identified. After removing any double counting, the
20 number of patent applications plus the patents from step 1 constitute the
21 size of the patent family.

22
23 Furthermore, *forward citations* provide information about how often a
24 patent has been cited by following patent applications. The citations are
25 an instrument to determine the scope of the patent right relative to prior art
26 in the field. Therefore all necessary citations are added to the application

1
2
3 by the patent examiner during the filing process. On the one hand, this
4 implies that not necessarily all innovations which draw on an existing
5 patent in fact acknowledge the reference. On the other hand, an external
6 patent examiner has the benefit of following a consistent and objective
7 patent citation practice. The number of forward citations provides some
8 information on the importance of the invention for future research in the
9 field and hence, will be another indicator of quality of a patent. When
10 constructing the number of forward citations, we only include citations
11 within a five-year-interval after the application date.
12
13
14
15
16
17
18
19

20
21 Last, we include the number of *technological classes* in the composite
22 quality index which have been shown by previous research to be an
23 indicator of technological quality (see Lerner (1994)). This is a measure
24 of the scope of application of the respective technology. The technological
25 classes are listed in the patent document and are eight digit codes of the
26 International Patent Classification (IPC) system.
27
28
29
30
31
32
33

34 In a previous step to the principal components analysis, the separate
35 quality indicators are regressed on the year of application and the main
36 technology class in a three stage least squares estimation procedure
37 to filter out any trends in time or industry. The residuals from this
38 first step are then used to estimate the factor model by maximum
39 likelihood estimation, assuming that the common component ν is
40 normally distributed. See also Lanjouw and Schankerman (2004) and Hall

et al. (2007) for a thorough discussion of the theoretical framework and the estimation procedure of the factor model.

Tables

Table A1: CFC Legislation in 2003

Country	CFC Dummy	Tax Haven Definition
Belgium	0	-
Czech Republic	0	-
Denmark	1	Effective tax <75 percent of Danish tax
Finland	1	Effective tax <60 percent of Finish tax
France	1	Effective tax <66 percent of French tax
Germany	1	Effective tax <25 percent
Great Britain	1	Effective tax <75 percent of British tax
Greece	0	-
Ireland	0	-
Italy	1	Black list
Luxembourg	0	-
Netherlands	0	-
Norway	1	Effective tax <66 percent of Norwegian tax
Poland	0	-
Portugal	1	Effective tax <60 percent of Portuguese tax
Spain	1	Effective tax <75 percent of Spanish tax
Sweden	1	Effective tax <55 percent of Swedish tax
Switzerland	0	-
Austria	0	-
Canada	1	Always binding
Japan	1	Effective tax <25 percent
United States	1	Effective tax <75 percent of US tax

Notes: CFC Dummy takes on the value 1 if the parent country has enacted CFC legislation and the value 0 otherwise. In the case of Norway, the 66 percent rule does not apply if a bilateral tax treaty exists between Norway and the country of the controlled subsidiary, unless the majority of the income in that subsidiary is passive. In the case of Italy, the black list of tax havens is too long to be reported, but it is based on and is very similar to the OECD tax haven list.

Table A2: Distribution of patents and tax rates by country

Notes: High quality patents are defined as patents with a composite quality index in the top quartile of all patents in our sample. The column 'Patent Income Tax Changes' denotes how often the patent income tax rate has changed within our sample period. 'Large Changes' include increases or decreases of at least 5 percentage points. Analogously, column 'TP Law Changes' captures any variation of the 'Transfer Price Regulation' index that is larger than 0.1.

Notes: The table presents coefficient estimates from the probit models described in the Results Section, run on the full sample of corporate patents. Standard errors in brackets below the coefficient estimates. ***, **, * indicates significance at the 1, 5, 10 percent significance level. See the notes to Table 1 for a definition of the variables. Macro controls is the vector of control variables described in the Data Section. 'Year Fixed Effects', 'Inv. Country Fixed Effects', 'Industry Fixed Effects' are full sets of year, inventor country and technology class fixed effects respectively. 'tax haven' indicates that the dependent variable is 1 for patients where ownership is geographically separated from the inventor location and assigned to a tax haven economy as defined in Dharmapala and Hines (2009), and zero otherwise. The dummy variable 'low tax' indicates if patent ownership is assigned to a country with a patent income tax in the lowest sample quartile in all sample years. The number of observations differ between the two sets of regressions as the sample is restricted to patients that were invented in a country within EU or OECD which is not a tax haven economy and not a low tax country respectively, following the above definitions.

Notes: This table presents coefficient estimates for all specifications in Table 2 with all regressors lagged by two years. Standard errors in brackets below the coefficient estimates. ***, **, * indicates significance at the 1, 5, 10% significance level. See the notes to Table 2 for a definition of the variables. Macro controls is the vector of control variables described in the Data Section. Year Fixed Effects, Industry Fixed Effects, Inventor country and technology class fixed effects respectively. Parent in Tax Haven indicates that the parent firm of the multinational group is located in a tax haven economy, following the **Dhammata and Hines (2009)** definition. Parent in Low Tax City indicates that the parent firm is located in a country with a patent income tax in the lowest sample quartile in all sample years. Tax Haven indicates that the dependent variable is 1 for patients where ownership is geographically separated from the inventor location and assigned to a tax haven economy as defined in **Dhammata and Hines (2009)**, and zero otherwise. The dummy variable low tax indicates if patient ownership is assigned to a country with a patent income tax in the lowest sample quartile in a sample year. The number of observations differ between the two sets of regressions as the sample is restricted to patients that were invented in a country within EU or OECD which is not a tax haven economy and not a low tax country respectively, following the above definitions.

Notes: The table reports elasticity estimates for the patent income tax rate ('tax rate'), the CFC-related tax component ('CFC') and the transfer pricing risk measure ('TP'). See also the variable definitions in Tables 3 and 4. The elasticities in Columns (2a)-(2d) refer to the model presented in Column (2) of Table 4 and the elasticities in Columns (8a)-(8c) analogously to the model in Column (8) of Table 4. Countries are indicated by their ISO code 2-abbreviations, see the notes to Table 3. Specifications (2a)-(2d) report the elasticities evaluated at different levels of 'Patent Quality (Composite Index)', namely -0.5, 0.5, 1.5 and 2.5.

24 Notes: The table reports the patent location
25 propensity per choice country based on the cur-
26 rent tax environment (i.e., current patent income
27 tax rates, CFC provisions and transfer pricing
28 scores). Choice countries are indicated by their
29 2-digit ISO code (see also the notes to Table 3).
